*args and **kwargs

Work with Python long enough, and eventually you will encounter `*args` and `**kwargs`. These strange terms show up as parameters in function definitions. What do they do? Let's review a simple function:

```
In [1]:  def myfunc(a,b):
             return sum((a,b))*.05

         myfunc(40,60)
```

Out[1]: 5.0

This function returns 5% of the sum of **a** and **b**. In this example, **a** and **b** are *positional* arguments; that is, 40 is assigned to **a** because it is the first argument, and 60 to **b**. Notice also that to work with multiple positional arguments in the `sum()` function we had to pass them in as a tuple.

What if we want to work with more than two numbers? One way would be to assign a *lot* of parameters, and give each one a default value.

```
In [2]:  def myfunc(a=0,b=0,c=0,d=0,e=0):
             return sum((a,b,c,d,e))*.05

         myfunc(40,60,20)
```

Out[2]: 6.0

Obviously this is not a very efficient solution, and that's where `*args` comes in.

*args

When a function parameter starts with an asterisk, it allows for an *arbitrary number* of arguments, and the function takes them in as a tuple of values. Rewriting the above function:

```
In [3]:  def myfunc(*args):
             return sum(args)*.05

         myfunc(40,60,20)
```

Out[3]: 6.0

Notice how passing the keyword "args" into the `sum()` function did the same thing as a tuple of arguments.

It is worth noting that the word "args" is itself arbitrary - any word will do so long as it's preceded by an asterisk. To demonstrate this:

```
In [4]:  def myfunc(*spam):
             return sum(spam)*.05

         myfunc(40,60,20)
```

```
Out[4]:  6.0
```

**kwargs

Similarly, Python offers a way to handle arbitrary numbers of *keyworded* arguments. Instead of creating a tuple of values, `**kwargs` builds a dictionary of key/value pairs. For example:

```
In [5]:  def myfunc(**kwargs):
             if 'fruit' in kwargs:
                 print(f"My favorite fruit is {kwargs['fruit']}")   # review String Formatt
             else:
                 print("I don't like fruit")

         myfunc(fruit='pineapple')
```

```
My favorite fruit is pineapple
```

```
In [6]:  myfunc()
```

```
I don't like fruit
```

*args and **kwargs combined

You can pass `*args` and `**kwargs` into the same function, but `*args` have to appear before `**kwargs`

```
In [7]:  def myfunc(*args, **kwargs):
             if 'fruit' and 'juice' in kwargs:
                 print(f"I like {' and '.join(args)} and my favorite fruit is {kwargs['fru
                 print(f"May I have some {kwargs['juice']} juice?")
             else:
                 pass

         myfunc('eggs','spam',fruit='cherries',juice='orange')
```

```
I like eggs and spam and my favorite fruit is cherries
May I have some orange juice?
```

Placing keyworded arguments ahead of positional arguments raises an exception:

```
In [8]:  myfunc(fruit='cherries',juice='orange','eggs','spam')
```

```
  File "<ipython-input-8-fc6ff65addcc>", line 1
    myfunc(fruit='cherries',juice='orange','eggs','spam')
                                           ^
SyntaxError: positional argument follows keyword argument
```

As with "args", you can use any name you'd like for keyworded arguments - "kwargs" is just a popular convention.

That's it! Now you should understand how `*args` and `**kwargs` provide the flexibilty to work with arbitrary numbers of arguments!

```
  File "<ipython-input-8-fc6ff65addcc>", line 1
    myfunc(fruit='cherries',juice='orange','eggs','spam')
                                           ^
SyntaxError: positional argument follows keyword argument
```
